1 The psych package

1.1 Preface

The psych package (Revelle, 2014) has been developed to include those functions most useful for teaching and learning basic psychometrics and personality theory. Functions have been developed for many parts of the analysis of test data, including basic descriptive statistics (describe and pairs.panels), dimensionality analysis (ICLUST, VSS, principal, factor.pa), reliability analysis (omega, guttman) and eventual scale construction (cluster.cor, score.items). The use of these and other functions is described in more detail in the accompanying vignette (overview.pdf) as well as in the complete user’s manual and the relevant help pages. (These vignettes are also available at http://personality-project.org/r/overview.pdf) and http://personality-project.org/r/psych_for_sem.pdf).

This vignette is concerned with the problem of modeling structural data and using the psych package as a front end for the much more powerful sem package of John Fox (Fox, 2006, 2009; Fox et al., 2013). Future releases of this vignette will include examples for using the lavaan package of Yves Rosseel (Rosseel, 2012).

The first section discusses how to simulate particular latent variable structures. The second considers several Exploratory Factor Analysis (EFA) solutions to these problems. The third section considers how to do confirmatory factor analysis and structural equation modeling using the sem package but with the input prepared using functions in the psych package.

1.2 Creating and modeling structural relations

One common application of psych is the creation of simulated data matrices with particular structures to use as examples for principal components analysis, factor analysis, cluster analysis, and structural equation modeling. This vignette describes some of the functions used for creating, analyzing, and displaying such data sets. The examples use two other packages: Rgraphviz and sem. Although not required to use the psych package, sem is required for these examples. Although Rgraphviz had been used for the graphical displays, it has now been replaced with graphical functions within psych. The analyses themselves require only the sem package to do the structural modeling.
2 Functions for generating correlational matrices with a particular structure

The \texttt{sim} family of functions create data sets with particular structure. Most of these functions have default values that will produce useful examples. Although graphical summaries of these structures will be shown here, some of the options of the graphical displays will be discussed in a later section.

The \texttt{sim} functions include:

\texttt{sim.structure} A function to combine a measurement and structural model into one data matrix. Useful for understanding structural equation models. Combined with \texttt{structure.diagram} to see the proposed structure.

\texttt{sim.congeneric} A function to create congeneric items/tests for demonstrating classical test theory. This is just a special case of \texttt{sim.structure}.

\texttt{sim.hierarchical} A function to create data with a hierarchical (bifactor) structure.

\texttt{sim.general} A function to simulate a general factor and multiple group factors. This is done in a somewhat more obvious, although less general, method than \texttt{sim.hierarcical}.

\texttt{sim.item} A function to create items that either have a simple structure or a circumplex structure.

\texttt{sim.circ} Create data with a circumplex structure.

\texttt{sim.dichot} Create dichotomous item data with a simple or circumplex structure.

\texttt{sim.minor} Create a factor structure for nvar variables defined by nfact major factors and $\frac{nvar}{2}$ “minor” factors for n observations.

\texttt{sim.parallel} Create a number of simulated data sets using \texttt{sim.minor} to show how parallel analysis works.

\texttt{sim.rasch} Create IRT data following a Rasch model.

\texttt{sim.irt} Create a two parameter IRT logistic (2PL) model.

\texttt{sim.anova} Simulate a 3 way balanced ANOVA or linear model, with or without repeated measures. Useful for teaching courses in research methods.

To make these examples replicable for readers, all simulations are prefaced by setting the random seed to a fixed (and for some, memorable) number (Adams, 1980). For normal use of the simulations, this is not necessary.
2.1 sim.congeneric

Classical test theory considers tests to be \( \tau \) equivalent if they have the same covariance with a vector of latent true scores, but perhaps different error variances. Tests are considered congeneric if they each have the same true score component (perhaps to a different degree) and independent error components. The \texttt{sim.congeneric} function may be used to generate either structure.

The first example considers four tests with equal loadings on a latent factor (that is, a \( \tau \) equivalent model). If the number of subjects is not specified, a population correlation matrix will be generated. If \( N \) is specified, then the sample correlation matrix is returned. If the “short” option is FALSE, then the population matrix, sample matrix, and sample data are all returned as elements of a list.

```r
> library(psych)
> set.seed(42)
> tau <- sim.congeneric(loads=c(.8,.8,.8,.8)) #population values
> tau.samp <- sim.congeneric(loads=c(.8,.8,.8,.8),N=100) # sample correlation matrix for 100 cases
> round(tau.samp,2)

V1   V2   V3   V4
V1 1.00 0.68 0.72 0.66
V2 0.68 1.00 0.65 0.67
V3 0.72 0.65 1.00 0.76
V4 0.66 0.67 0.76 1.00

> tau.samp <- sim.congeneric(loads=c(.8,.8,.8,.8),N=100, short=FALSE)
> tau.samp

Call: NULL

$model (Population correlation matrix)

V1  V2  V3  V4
V1 1.00 0.64 0.64 0.64
V2 0.64 1.00 0.64 0.64
V3 0.64 0.64 1.00 0.64
V4 0.64 0.64 0.64 1.00

$r (Sample correlation matrix for sample size = 100)

V1  V2  V3  V4
V1 1.00 0.70 0.62 0.58
V2 0.70 1.00 0.65 0.64
V3 0.62 0.65 1.00 0.59
V4 0.58 0.64 0.59 1.00

> dim(tau.samp$observed)

[1] 100 4

In this last case, the generated data are retrieved from tau.samp$observed. Congeneric data are created by specifying unequal loading values. The default values are loadings of c(.8,.7,.6,.5). As seen in Figure 1, \( \tau \) equivalence is the special case where all paths are equal.
Figure 1: Tau equivalent tests are special cases of congeneric tests. Tau equivalence assumes $a=b=c=d$. 

![Structural model diagram]
2.2 sim.hierarchical

The previous function, sim.congeneric, is used when one factor accounts for the pattern of correlations. A slightly more complicated model is when one broad factor and several narrower factors are observed. An example of this structure might be the structure of mental abilities, where there is a broad factor of general ability and several narrower factors (e.g., spatial ability, verbal ability, working memory capacity). Another example is in the measure of psychopathology where a broad general factor of neuroticism is seen along with more specific anxiety, depression, and aggression factors. This kind of structure may be simulated with sim.hierarchical specifying the loadings of each sub factor on a general factor (the g-loadings) as well as the loadings of individual items on the lower order factors (the f-loadings). An early paper describing a bifactor structure was by Holzinger and Swineford (1937). A helpful description of what makes a good general factor is that of Jensen and Weng (1994).

For those who prefer real data to simulated data, six data sets are included in the bifactor data set. One is the original 14 variable problem of Holzinger and Swineford (1937) (holzinger), a second is a nine variable problem adapted by Bechtoldt (1961) from Thurstone and Thurstone (1941) (the data set is used as an example in the SAS manual and discussed in great detail by McDonald (1999)), a third is from a recent paper by Reise et al. (2007) with 16 measures of patient reports of interactions with their health care provider.

```r
> set.seed(42)
> gload=matrix(c(.9,.8,.7),nrow=3)
> fload <- matrix(c(.8,.7,.6,rep(0,9),.7,.6,.5,
+ rep(0,9),.7,.6,.4), ncol=3)
> fload #echo it to see the structureSw

V7 0.35 0.31 0.26 0.27 0.24 0.20 1.00 0.42 0.28
```
These data can be represented as either a *bifactor* (Figure 2 panel A) or *hierarchical* (Figure 2 Panel B) factor solution. The analysis was done with the `omega` function.

### 2.3 sim.item and sim.circ

Many personality questionnaires are thought to represent multiple, independent factors. A particularly interesting case is when there are two factors and the items either have *simple structure* or *circumplex structure*. Examples of such items with a circumplex structure are measures of emotion (Rafaeli and Revelle, 2006) where many different emotion terms can be arranged in a two dimensional space, but where there is no obvious clustering of items. Typical personality scales are constructed to have simple structure, where items load on one and only one factor.

An additional challenge to measurement with emotion or personality items is that the items can be highly skewed and are assessed with a small number of discrete categories (do not agree, somewhat agree, strongly agree).

The more general `sim.item` function, and the more specific, `sim.circ` functions simulate items with a two dimensional structure, with or without skew, and varying the number of categories for the items. An example of a circumplex structure is shown in Figure 3.

### 2.4 sim.structure

A more general case is to consider three matrices, \( \vec{f}_x, \vec{\phi}_{xy}, \vec{f}_y \) which describe, in turn, a measurement model of x variables, \( \vec{f}_x \), a measurement model of y variables, \( \vec{f}_y \), and a covariance matrix between and within the two sets of factors. If \( \vec{f}_x \) is a vector and \( \vec{f}_y \) and \( \vec{\phi}_{xy} \) are NULL, then this is just the congeneric model. If \( \vec{f}_x \) is a matrix of loadings with n rows and c columns, then this is a measurement model for n variables across c factors. If \( \vec{\phi}_{xy} \) is not null, but \( \vec{f}_y \) is NULL, then the factors in \( \vec{f}_x \) are correlated. Finally, if all three matrices are not NULL, then the data show the standard linear structural relations (LISREL) structure.

Consider the following examples:

#### 2.4.1 \( \vec{f}_x \) is a vector implies a congeneric model

```r
> set.seed(42)
> fx <- c(.9,.8,.7,.6)
```
A bifactor model

A hierarchical model

Figure 2: (Left panel) A bifactor solution represents each test in terms of a general factor and a residualized group factor. (Right Panel) A hierarchical factor solution has g as a second order factor accounting for the correlations between the first order factors.
> circ <- sim.circ(16)
> f2 <- fa(circ,2)
> plot(f2,title="16 simulated variables in a circumplex pattern")

Figure 3: Emotion items or interpersonal items frequently show a circumplex structure. Data generated by sim.circ and factor loadings found by the principal axis algorithm using factor.pa.
2.4.2 $\mathbf{f}_x$ is a matrix implies an independent factors model:

2.4.3 $\mathbf{f}_x$ is a matrix and $\mathbf{Phi} \neq I$ is a correlated factors model
Figure 4: Three uncorrelated factors generated using the sim.structure function and drawn using structure.diagram.
Using symbolic loadings and path coefficients  For some purposes, it is helpful not to specify particular values for the paths, but rather to think of them symbolically. This can be shown with symbolic loadings and path coefficients by using the `structure.list` and `phi.list` functions to create the `fx` and `Phi` matrices (Figure 5).

```r
> fxs <- structure.list(9, list(F1=c(1,2,3), F2=c(4,5,6), F3=c(7,8,9)))
> Phis <- phi.list(3, list(F1=c(2,3), F2=c(1,3), F3=c(1,2)))
> fxs  # show the matrix
    F1 F2 F3
[1,] "a1" "0" "0"
[2,] "a2" "0" "0"
[3,] "a3" "0" "0"
[4,] "0" "b4" "0"
[5,] "0" "b5" "0"
[6,] "0" "b6" "0"
[7,] "0" "0" "c7"
[8,] "0" "0" "c8"
[9,] "0" "0" "c9"
> Phis  # show this one as well
    F1 F2 F3
F1 "1" "rba" "rca"
```
F2 "rab" "1"  "rcb"
F3 "rac" "rbc" "1"

The `structure.list` and `phi.list` functions allow for creation of fx, Phi, and fy matrices in a very compact form, just by specifying the relevant variables.

```r
> #plot.new()
> corf3.mod <- structure.diagram(fxs,Phis)
```

**Structural model**

![Structural model diagram]

Figure 5: Three correlated factors with symbolic paths. Created using `structure.diagram` and `structure.list` and `phi.list` for ease of input.

**Drawing path models from Exploratory Factor Analysis solutions** Alternatively, this result can represent the estimated factor loadings and oblique correlations found using `factanal` (Maximum Likelihood factoring) or `fa` (Principal axis or minimum residual (minres) factoring) followed by a promax rotation using the `Promax` function (Figure 6.)
Comparing this figure with the previous one (Figure 5), it will be seen that one path was dropped because it was less than the arbitrary “cut” value of .2.

```r
> f3.p <- Promax(fa(cor.f3$model,3))
> #plot.new()
> mod.f3p <- structure.diagram(f3.p, cut=.2)
```

Figure 6: The empirically fitted structural model. Paths less than cut (.2 in this case, the default is .3) are not shown.

2.4.4 $\vec{f}_x$ and $\vec{f}_y$ are matrices, and $\Phi \neq I$ represents their correlations

A more complicated model is when there is a $\vec{f}_y$ vector or matrix representing a set of Y latent variables that are associated with the a set of y variables. In this case, the Phi matrix is a set of correlations within the X set and between the X and Y set.
```r
> set.seed(42)
> fx <- matrix(c(.9,.8,.7,rep(0,9),.7,.6,.5,rep(0,9),.6,.5,.4), ncol=3)
> fy <- c(.6,.5,.4)
> Phi <- matrix(c(1,.48,.32,.4,.48,1,.32,.3,.3,.32,1,.2,.4,.3,.2,1), ncol=4)
> twelveV <- sim.structure(fx,Phi, fy)$model
> colnames(twelveV) <-rownames(twelveV) <- c(paste("x",1:9,sep=""),paste("y",1:3,sep=""))
> round(twelveV,2)

Data with this structure may be created using the `sim.structure` function, and shown either with the numeric values or symbolically using the `structure.diagram` function (Figure 7).

```r
gfx <- structure.list(9,list(X1=c(1,2,3), X2 =c(4,5,6),X3 = c(7,8,9)))
> phi <- phi.list(4,list(F1=c(4),F2=c(4),F3=c(4),F4=c(1,2,3)))
> fyx <- structure.list(3,list(Y=c(1,2,3)),"Y")

```r

2.4.5 A hierarchical structure among the latent predictors.

Measures of intelligence and psychopathology frequently have a general factor as well as multiple group factors. The general factor then is thought to predict some dependent latent variable. Compare this with the previous model (see Figure 7).

These two models can be compared using structural modeling procedures (see below).

3 Exploratory functions for analyzing structure

Given correlation matrices such as those seen above for congeneric or bifactor models, the question becomes how best to estimate the underlying structure. Because these data sets were generated from a known model, the question becomes how well does a particular model recover the underlying structure.
Figure 7: A symbolic structural model. Three independent latent variables are regressed on a latent Y.
> fxh <- structure.list(9,list(X1=c(1:3),X2=c(4:6),X3=c(7:9),g=NULL))
> fy <- structure.list(3,list(Y=c(1,2,3)))
> Phi <- diag(1,5,5)
> Phi[4,c(1:3)] <- letters[1:3]
> Phi[5,4] <- "r"
> #plot.new()
> hi.mod <- structure.diagram(fxh,Phi, fy)

Structural model

Figure 8: A symbolic structural model with a general factor and three group factors. The general factor is regressed on the latent Y variable.
3.1 Exploratory simple structure models

The technique of principal components provides a set of weighted linear composites that best approximates a particular correlation or covariance matrix. If these are then rotated to provide a more interpretable solution, the components are no longer the principal components. The `principal` function will extract the first n principal components (default value is 1) and if n>1, rotate to simple structure using a varimax, quartimin, or Promax criterion.

```r
> principal(cong1$model)
Prinicipal Components Analysis

</tr>
</thead>
<tbody>
<tr>
<td>Correlation of scores with factors</td>
</tr>
<tr>
<td>Multiple R square of scores with factors</td>
</tr>
<tr>
<td>Minimum correlation of possible factor scores</td>
</tr>
</tbody>
</table>

It is important to note that although the principal components function does not exactly reproduce the model parameters, the factor.pa function, implementing principal axes or minimum residual (minres) factor analysis, does.

Consider the case of three underlying factors as seen in the bifact example above. Because the number of observations is not specified, there is no associated $\chi^2$ value. The factor.congruence function reports the cosine of the angle between the factors.

```r
> pc3 <- principal(bifact,3)
> pa3 <- fa(bifact,3,fm="pa")
> ml3 <- fa(bifact,3,fm="ml")

By default, all three of these procedures use the varimax rotation criterion. Perhaps it is useful to apply an oblique transformation such as Promax or oblimin to the results. The Promax function in psych differs slightly from the standard promax in that it reports the factor intercorrelations.

### 3.2 Exploratory hierarchical models

In addition to the conventional oblique factor model, an alternative model is to consider the correlations between the factors to represent a higher order factor. This can be shown either as a **bifactor** solution Holzinger and Swineford (1937); Schmid and Leiman (1957) with a general factor for all variables and a set of residualized group factors, or as a hierarchical structure. An exploratory hierarchical model can be applied to this kind of data structure using the **omega** function. Graphic options include drawing a Schmid - Leiman bifactor solution (Figure 9) or drawing a hierarchical factor solution f(Figure 10).

#### 3.2.1 A bifactor solution

The **bifactor** solution has a general factor loading for each variable as well as a set of residual group factors. This approach has been used extensively in the measurement of ability and has more recently been used in the measure of psychopathology (Reise et al., 2007). Data sets included in the **bifactor** data include the original (Holzinger and Swineford, 1937) data set (holzinger) as well as a set from Reise et al. (2007) (reise) and a nine variable problem from Thurstone.

#### 3.2.2 A hierarchical solution

Both of these graphical representations are reflected in the output of the **omega** function. The first was done using a Schmid-Leiman transformation, the second was not. As will be seen later, the objects returned from these two analyses may be used as models for a **sem** analysis. It is also useful to examine the estimates of reliability reported by **omega**.

```r
> om.bi
Omega
Call: omega(m = bifact)
Alpha: 0.78
G.6: 0.78
Omega Hierarchical: 0.7
Omega H asymptotic: 0.85
```

Yet one more way to treat the hierarchical structure of a data set is to consider hierarchical cluster analysis using the ICLUST algorithm (Figure 11). ICLUST is most appropriate for forming item composites.

Hierarchical cluster analysis of bifact data

Figure 11: A hierarchical cluster analysis of the bifact data set using ICLUST
4  Confirmatory models

Although the exploratory models shown above do estimate the goodness of fit of the model and compare the residual matrix to a zero matrix using a $\chi^2$ statistic, they estimate more parameters than are necessary if there is indeed a simple structure, and they do not allow for tests of competing models. The `sem` function in the `sem` package by John Fox allows for confirmatory tests. The interested reader is referred to the `sem` manual for more detail (Fox et al., 2013).

4.1 Using psych as a front end for the sem package

Because preparation of the `sem` commands is a bit tedious, several of the `psych` package functions have been designed to provide the appropriate commands. That is, the functions `structure.list`, `phi.list`, `structure.diagram`, `structure.sem`, and `omega.graph` may be used as a front end to `sem`. Usually with no modification, but sometimes with just slight modification, the model output from the `structure.diagram`, `structure.sem`, and `omega.graph` functions is meant to provide the appropriate commands for `sem`.

4.2 Testing a congeneric model versus a tau equivalent model

The congeneric model is a one factor model with possibly unequal factor loadings. The tau equivalent model model is one with equal factor loadings. Tests for these may be done by creating the appropriate structures. The `structure.graph` function which requires `Rgraphviz`, or `structure.diagram` or the `structure.sem` functions which do not may be used.

The following example tests the hypothesis (which is actually false) that the correlations found in the cong data set (see 2.1) are tau equivalent. Because the variable labels in that data set were V1 ... V4, we specify the labels to match those.

```r
> library(sem)
> mod.tau <- structure.sem(c("a","a","a","a"),labels=paste("V",1:4,sep=""))
> mod.tau #show it

The anova comparison of the congeneric versus tau equivalent model shows that the change in $\chi^2$ is significant given the change in degrees of freedom.

4.3 Testing the dimensionality of a hierarchical data set by creating the model

The bifact correlation matrix was created to represent a hierarchical structure. Various confirmatory models can be applied to this matrix.

The first example creates the model directly, the next several create models based upon exploratory factor analyses. mod.one is a congeneric model of one factor accounting for the relationships between the nine variables. Although not correct, with 100 subjects, this model can not be rejected. However, an examination of the residuals suggests serious problems with the model.

> mod.one <- structure.sem(letters[1:9],labels=paste("V",1:9,sep=""))
> mod.one #show the model

4.4 Testing the dimensionality based upon an exploratory analysis

Alternatively, the output from an exploratory factor analysis can be used as input to the `structure.sem` function.

```r
> f1 <- factanal(covmat=bifact, factors=1)
> mod.f1 <- structure.sem(f1)
> sem.f1 <- sem(mod.f1, bifact, 100)
> sem.f1

Model Chisquare = 21.16848 Df = 27

V1  V2  V3  V4  V5  V6  V7  V8
0.7507129 0.6726412 0.5811209 0.5737425 0.5021915 0.4239908 0.5067957 0.4450171
V9 x1e x2e x3e x4e x5e x6e x7e
0.3052415 0.4364302 0.5475539 0.6622982 0.6708197 0.7478036 0.8202314 0.7431581
x8e x9e
0.8019593 0.9068284

Iterations = 11

The answers are, of course, identical.

4.5 Specifying a three factor model

An alternative model is to extract three factors and try this solution. The `fa` factor analysis function (using the `minimum residual` algorithm) is used to detect the structure. Alternatively, the `factanal` could have been used. Rather than use the default rotation of `oblimin`, we force an orthogonal solution (even though we know it will be a poor solution).

```r
> f3 <- fa(bifact, 3, rotate="varimax")
> mod.f3 <- structure.sem(f3)
> sem.f3 <- sem(mod.f3, bifact, 100)
> summary(sem.f3, digits=2)

Model Chisquare = 53.86635 Df = 27 Pr(>Chisq) = 0.001579738
AIC = 89.86635
BIC = -70.47325

32
The residuals show serious problems with this model. Although the residuals within each of the three factors are zero, the residuals between groups are much too large.

### 4.6 Allowing for an oblique solution

The previous solution is clearly very bad. What would happen if the exploratory solution were allowed to have correlated (oblique) factors?

```r
> f3 <- fa(bifact, 3)  # extract three factors and do an oblique rotation
> mod.f3 <- structure.sem(f3)  # create the sem model
> mod.f3  # show it
```

```r
The residuals show serious problems with this model. Although the residuals within each of the three factors are zero, the residuals between groups are much too large.
```
The structure being tested may be seen using `structure.graph`

Figure 12: A three factor, oblique solution.
This makes much better sense, and in fact (as hoped) recovers the original structure.

4.7 Extract a bifactor solution using \texttt{omega} and then test that model using \texttt{sem}

A bifactor solution has previously been shown (Figure 9). The output from the \texttt{omega} function includes the \texttt{sem} commands for the analysis. As an example of doing this with real rather than simulated data, consider 9 variables from Thurstone. For completeness, the \texttt{stdCoef} from \texttt{sem} is used as well as the \texttt{summary} function.

4.7.1 \texttt{sem} of Thurstone 9 variable problem

The \texttt{sem} manual includes an example of a hierarchical solution to 9 mental abilities originally reported by Thurstone and used in the SAS manual for PROC CALIS and discussed in detail by McDonald (1999). The data matrix, as reported by Fox may be found in the \texttt{Thurstone} data set (which is “lazy loaded”). Using the commands just shown, it is possible to analyze this data set using a bifactor solution (Figure 13).

```r
> sem.bi <- sem(om.th.bi$model,Thurstone,213) #use the model created by omega
> summary(sem.bi,digits=2)

Model Chisquare = 24.2163  Df = 18  Pr(>Chisq) = 0.1480685

Compare this solution to the one reported below, and to the `sem` manual.

### 4.8 Examining a hierarchical solution

A hierarchical solution to this data set was previously found by the `omega` function (Figure 10). The output of that analysis can be used as a model for a `sem` analysis. Once again, the `stdCoef` function helps see the structure. Alternatively, using the `omega` function on the `Thurstone` data will create the model for this particular data set.

```r
> sem.hi <- sem(om.hi$model,Thurstone,213)
> summary(sem.hi,digits=2)
```

```

\[\text{stdCoef(sem.hi,digits=2)}\]
Using the Thurstone data set, we see what happens when a hierarchical model is applied to real data. The exploratory structure derived from the omega function (Figure 14) provides estimates in close approximation to those found using sem. The model definition created by using omega is the same hierarchical model discussed in the sem help page. The bifactor model, with 6 more parameters does provide a better fit to the data than the hierarchical model.

Similar analyses can be done with other data that are organized hierarchically. Examples of these analyses are analyzing the 14 variables of holzinger and the 16 variables of reise. The output from the following analyses has been limited to just the comparison between the bifactor and hierarchical solutions.
4.9 Estimating Omega using EFA followed by CFA

The function `omegaSem` combines both an exploratory factor analysis using `omega`, then calls the appropriate `sem` functions and organizes the results as in a standard `omega` analysis.

An example is found from the Thurstone data set of 9 cognitive variables:

```r
> om.sem <- omegaSem(Thurstone,n.obs=213)
```

Call: `omegaSem(m = Thurstone, n.obs = 213)`

Omega

Call: `omega(m = m, nfactors = nfactors, fm = fm, key = key, flip = flip, digits = digits, title = title, sl = sl, labels = labels, plot = plot, n.obs = n.obs, rotate = rotate, Phi = Phi, option = option)`

Alpha: 0.89

G.6: 0.91

Omega Hierarchical: 0.74

Omega H asymptotic: 0.79

Omega Total 0.93

Schmid Leiman Factor loadings greater than 0.2

general/max 3.71 max/min = 1.35

mean percent general = 0.6 with sd = 0.05 and cv of 0.09

Explained Common Variance of the general factor = 0.6

The degrees of freedom are 12 and the fit is 0.01

The number of observations was 213 with Chi Square = 2.82 with prob < 1

The root mean square of the residuals is 0.01

The df corrected root mean square of the residuals is 0.01

RMSEA index = 0 and the 90 % confidence intervals are  NA  NA

BIC = 61.51

Compare this with the adequacy of just a general factor and no group factors

The degrees of freedom for just the general factor are 27 and the fit is 1.48

The number of observations was 213 with Chi Square = 307.1 with prob < 2.8e-49

The root mean square of the residuals is 0.14

The df corrected root mean square of the residuals is 0.16

RMSEA index = 0.224 and the 90 % confidence intervals are 0.199 0.243

BIC = 162.35

Comparing the two models graphically (Figure 15 with Figure 13 shows that while not identical, they are very similar. The sem version is basically a forced simple structure. Notice that the values of $\omega_h$ are not identical from the EFA and CFA models. The CFA solution yields higher values of $\omega_h$ because, by forcing a pure cluster solution (no cross loadings), the correlations between the factors is forced to be through the $g$ factor.

5 Summary and conclusion

The use of exploratory and confirmatory models for understanding real data structures is an important advance in psychological research. To understand these approaches it is helpful to try them first on “baby” data sets. To the extent that the models we use can be tested on simple, artificial examples, it is perhaps easier to practice their application. The psycho tools for simulating structural models and for specifying models are a useful supplement to the power of packages such as sem. The techniques that can be used on simulated data set can also be applied to real data sets.
