# Psychology 405: Psychometric Theory Scale Construction: an example 

William Revelle

Department of Psychology
Northwestern University
Evanston, Illinois USA

May, 2012

## Outline

(1) Steps towards scale construction
(2) A demonstration
(3) Preliminary steps

- Data checking

4 Score the scales
(5) Determining how many constructs are in a set of items
(6) Scoring the alternative solutions
(7) Show the items

## Scale construction: A 10 steps program

(1) Personality scales are not created in a theoretical vacuum. Perhaps the most important step in developing a new scale is a consideration of what is the construct of interest. What is it, what are manifestations of it, what is it not, and what should it not relate to.
(2) Then, what is the population of interest? Are they young old, highly literate, or somewhat challenged by literacy. Write items suitable for the population of interest.
(3) Give the items to the participants. Make sure that they are engaged in the task.

## Scale construction: A 10 steps program (continued)

(9) To analyze the data, it is necessary to enter the data into a machine readable form.

- This is a source of error. Double check for data entry errors.
- Double entry (two different people enter the data and then the two files are automatically compared) is recommended.
- Even better is automatic data entry (but then you need to check and double check the program).
- my.data <- read.table(myfile)
- my.data <- read.clipboard()
(5) Run basic descriptive statistics to do one more check for errors. Graphically check as well.
- describe()
- pairs.panels()
(0) Form the variance/covariance matrix from the items and examine the dimensionality of the resulting space.

## Scale construction: A 10 steps program (continued)

(1) Apply various data reduction techniques (factor analysis, principal components analysis, cluster analysis).

- fa
- principal
- iclust
(8) Form composite scales of the selected items. Check these scales for various measures of internal consistency.
- make.keys
- score.items
(9) Discriminant validity requires that the scales not correlate with other, unrelated traits.
(10) Convergent validity requires that the scale do correlate with other, alternative measures of the same trait.

## Basic item development

As a demonstration of scale construction and validation, consider the following problem. N self report items are given to a number of people. This inventory has is composed of subsets of items that measure believed to measure different traits. In addition, each subject is rated by a friend on those same traits. There are several questions we can ask of these data:
(1) Do the items form reliable scales?
(2) What are the correlations of these scales?
(3) Do the scales correlate with the peer ratings?
(9) Can we empirically find a better structure of the items?
(6) Do these revised scales show greater independence, reliability, and validity?

## Item writing

To show the procedures, 14 students in a personality research course spent several weeks learning about each of four personality dimensions. Each student then wrote five items to assess each of four constructs.
(1) Need for Achievement
(2) Anxiety
(3) Sociability
(1) Impulsivity

As a group they examined all of the items and formed the best 84 items into one questionnaire with 21 items believed to measure each of the constructs. They administered this questionnaire to approximately ten friends each whom they also rated on these four constructs. Thus, we have a data set of about 140 participants assessed on 88 items (the 84 self report items and the 4 peer ratings). These four sets of items can be seen as samples from four domains.

## Initial data reading

The data, item labels, and scoring keys are saved on a web server. They may be accessed by the read.table(file.name) command. We then use the dim command to find out the dimensions of the data file as well as the names command to find out what the names are.

```
prq.data.name <- "http://personality-project.org/revelle/syllabi/301/prq.data"
prq.keys.name <- "http://personality-project.org/revelle/syllabi/301/prq.keys"
prq.labels.name <- "http://personality-project.org/revelle/syllabi/301/prq.labels"
prq.data <- read.table(prq.data.name, header=TRUE)
prq.keys <- read.table(prq.keys.name, header=TRUE)
prq.labels <- read.table(prq.labels.name,header=TRUE)
dim(prq.data)
names(prq.data)
#only 75 subjects!
[1] 75 91
> names(prq.data)
\begin{tabular}{llllll} 
[1] & "Exp" & "Subject" & "NeedAch" & "Anxiety" & "Sociability" "Impulsivity" \\
[7] & "Gender" & "q1" & "q2" & "q3" & "q4" \\
[13] & "q6" & "q7" & "q8" & "q9" & "q10" \\
[19] & "q12" & "q13" & "q14" & "q15" & "q16" \\
[25] "q18" & "q19" & "q20" & "q21" & "q17" \\
[31] "q24" & "q25" & "q26" & "q27" & "q28" & "q23" \\
[37] "q30" & "q31" & "q32" & "q33" & "q34" & "q29" \\
\(\ldots\) & & & "q35" \\
[85] "q78" & "q79" & "q80" & "q81" & "q82" & "q83"
\end{tabular}
```

## Data checking

The first two variables are not particularly interesting, so we create a new data.frame without them. Then find the descriptive statistics of the data in order to make sure that the data were entered correctly.

```
> prq.items <- prq.data[,-c(1:2)]
> describe(prq.items)
```

## Data checking

In doing this, we discovered (on the first pass through the data) that one of the variables had a range of 32 rather than the 6 that was appropriate. Correcting the data, we can start over again.
Even with well meaning, careful data entry, mistakes will happen in data entry. It is recommended that data be entered twice and then compared using software that compares the two files line by line and entry by entry. In all cases, make sure to describe the data and check that the ranges are appropriate for the data.
Thus, the data were edited and the prior steps were done again until there were no incorrectly entered subjects. One error that makes data checking complicated is a blank field in Excel is read improperly. Using NA to specify not available is better. Note that the describe output shows that some variables do not have as many subjects as others.

## Score the scales

(1) Forming scale scores as linear sums (or averages) of the items is easy to do in R.
(2) One technique (not recommended) is to do a series of recodings, creating new variables for each scale.
(3) A simpler technique, using the score.items function from the psych package does this for all scales defined in a matrix of keys (the keys matrix).
(9) This is essentially a matrix of $-1,0$, and $1 s$ where 0 means don't include the item in the scale, and a 1 means to include it. -1 means to reverse key the item.

## A keys matrix

> prq.keys

|  | PNach | PAnx | PSoc | PImp | G | Nach | Anx | Soc | Imp |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | ---: |
| 1 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| 2 | 0 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| 3 | 0 | 0 | 1 | 0 | 0 | 0 | 0 | 0 | 0 |
| 4 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 0 | 0 |
| 5 | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 0 |
| 6 | 0 | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 0 |
| 7 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 0 | 0 |
| 8 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 0 |
| 9 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | -1 |
| $\ldots$ |  |  |  |  |  |  |  |  |  |
| 84 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | -1 | 0 |
| 85 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 |
| 86 | 0 | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 0 |
| 87 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 0 | 0 |
| 88 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 0 |
| 89 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 |

## Making a keys matrix

Although it is possible to make up a keys matrix in Excel and copy it into $R$, it is easier to use the make.keys function.

```
> my.keys <- make.keys(nvars=89,keys.list =list(Pnach=1,PAnx=2,PSoc=3,PImp=4,G=5,
                                Nach=c (6,10,14,18),Anx=c(7,11, 15,19),Soc=c(8,12,-16,20), Imp=c (-9,13,-17, 21)))
> my.keys
```

| [1,] | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| [2,] | 0 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| [3,] | 0 | 0 | 1 | 0 | 0 | 0 | 0 | 0 | 0 |
| [4, ] | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 0 | 0 |
| [5,] | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 0 |
| [6, ] | 0 | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 0 |
| [7, ] | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 0 | 0 |
| [8,] | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 0 |
| [9,] | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | -1 |
| [10,] | 0 | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 0 |
| [11,] | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 0 | 0 |
| [12,] | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 0 |
| [13,] | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 |
| [14,] | 0 | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 0 |
| [15,] | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 0 | 0 |
| [16,] | 0 | 0 | 0 | 0 | 0 | 0 | 0 | -1 | 0 |
| [17,] | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | -1 |
| [18,] | 0 | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 0 |
| [19,] | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 0 | 0 |
| [20,] | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 0 |
| [21,] | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 |

## Score the items

We use the score.items function.
We first do this just for the items. The item.scores is a list of multiple values:
(1) scores - the actual scores for each subject
(2) missing - where there any missing values for any subject?
(3) alpha - coefficient alpha for each scale
(9) av.r - the average $r$ within each scale
(5) n.items - how many items in each scale?
(0) item.cor - the correlation of each item with each scale
(3) cor - the correlation matrix of the scales
(3) corrected - the raw correlations of the scales (below the diagonal), the alpha reliabilities (on the diagonal), and the intercorrelations corrected for unreliability (above the diagonal).

## Using score.items

```
> tem.scores <- score.items(prq.keys[,6:9],prq.items)
> print(item.scores$corrected)
> round(item.scores$corrected,2)
> print(item.scores$corrected)
    Nach Anx Soc Imp
Nach 0.83928271 0.08193167 0.2755535 -0.22602236
Anx 0.06805717 0.82212135 -0.2545185 0.09498796
Soc 0.23857492 -0.21809815 0.8931604 0.44321814
Imp -0.19259110 0.08010640 0.3895946 0.86509005
```

\#rounding to 2 decimal places is nicer

|  | Nach | Anx | Soc | Imp |
| :--- | ---: | ---: | ---: | ---: |
| Nach | 0.84 | 0.08 | 0.28 | -0.23 |
| Anx | 0.07 | 0.82 | -0.25 | 0.09 |
| Soc | 0.24 | -0.22 | 0.89 | 0.44 |
| Imp | -0.19 | 0.08 | 0.39 | 0.87 |

## Show more of the output

```
> item.scores
Call: score.items(keys = prq.keys[, 6:9], items = prq.items)
(Unstandardized) Alpha:
    Nach Anx Soc Imp
alpha 0.84 0.82 0.89 0.87
Average item correlation:
        Nach Anx Soc Imp
average.r 0.2 0.18 0.28 0.23
    Guttman 6* reliability:
        Nach Anx Soc Imp
Lambda.6 0.93 0.89 0.93 0.92
Scale intercorrelations corrected for attenuation
    raw correlations below the diagonal, alpha on the diagonal
    corrected correlations above the diagonal:
            Nach Anx Soc Imp
Nach 0.839 0.082 0.28 -0.226
Anx 0.068 0.822 -0.25 0.095
Soc 0.239 -0.218 0.89 0.443
Imp -0.193 0.080 0.39 0.865
    In order to see the item by scale loadings and frequency counts of the data
    print with the short option = FALSE

\hline
\end{tabular}

\section*{Show the MMTM matrix graphically}

\section*{Factor Analysis}

The items analysed were meant to represent four constructs. Given the previous analysis, they probably do. But what if we did not know how many separate dimensions were in the data? Is it possible to find out? Three alternative procedure address this question.
(1) Principal componenents analysis
(2) Factor analysis
(3) Cluster analysis

All three of these procedures are attempting to approximate the nvar * nvar correlation matrix R with a matrix of lesser rank, one that is nvar * nf. That is, can we find a Factor (Component or Cluster) such that
\[
\begin{equation*}
R \approx F F^{\prime}+U^{2} \tag{1}
\end{equation*}
\]

\section*{Factor analysis of PRQ}
(1) More items than people makes the matrix not invertible
(2) Can be solved by the fa function using minres option
(3) How many factors to extract?
- VSS(prq.items)
- Use VSS 3 ( complexity 1) or 4 (complexity 2)
- Use MAPS 8
(9) Theory says 4

\section*{VSS of prq}
